Final Report

ES-ESP5200 Modern Embedded Systems programming Coursework 2020

Design, development , testing and evaluation of Slot Machine

Biplav Karna

November 5, 2020

Chapter 1

Introduction

Slot machine is a game device easily available at every game parlour and casino. Figure 1.1 shows a slot machine. It has 3 spinning wheels, lever to start the spin, place to insert coin, display to show progress. It has some lighting effects and sound effects.

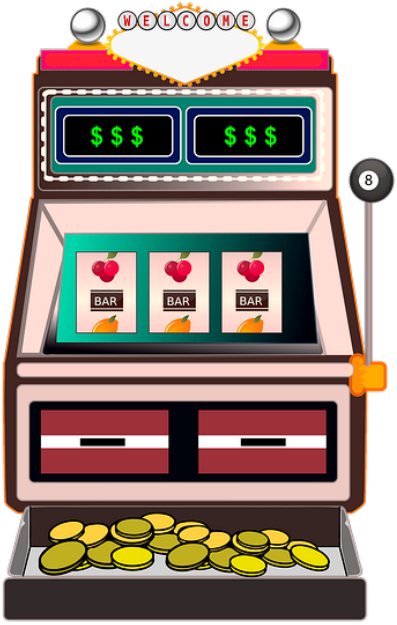

Figure 1.1: General Slot Machine, PHOTO SRC: pixabay.com

This can be mimicked with avr 2560 with LCD screen, buttons, leds and speaker/buzzer.

Chapter 2

Design

Slot machine is implemented using below components

- MEGA 2560 board
- 16 * 2 LCD
- 10 LEDs
- 4 * 4 Keypad (using only 2 button)
- supporting connections and components

The circuit diagram of the implementation is shown in the figure 2.1. PA0-PA7 are used for data bus, and PG0-PG2 are used for control bus for LCD interfacing. PB0-PB7 are used for LEDs. PD1-PD0 are connected to two buttons for spin and bet functions. PD1-PD0 are used as external interrupts.

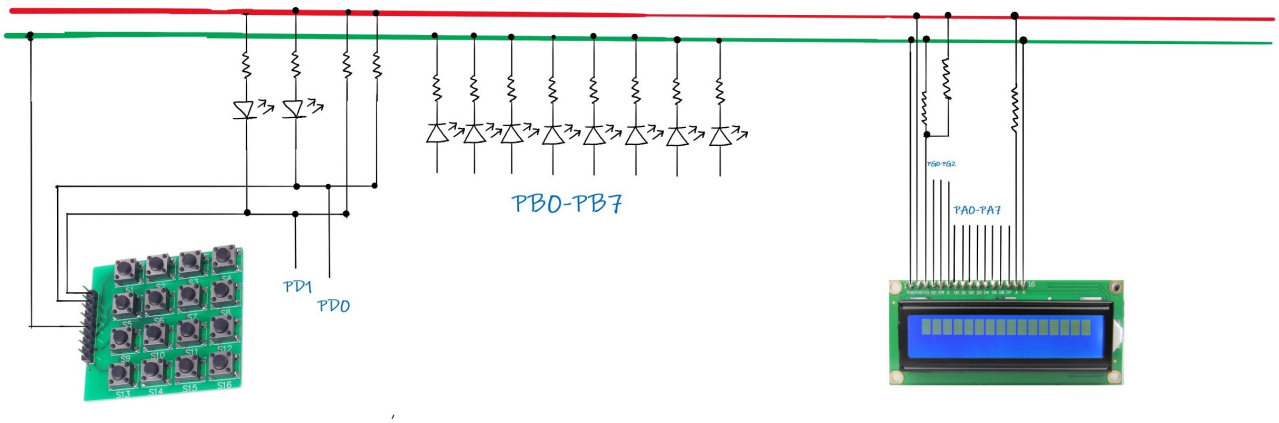

Figure 2.1: Circuit Diagram

The life-size slot machine's spin and bet levers are realized by buttons. The life-size screen is realized by LCD. The LCD is divided into four sections:- bet section, balance section, winning amount section and wheel section. Figure 2.2 shows the division of section on LCD. The lighting effect is realized with 8 leds. The initial balance is set to 2000. Default bet value is 1. The three wheels of slot machine is represented by 3 led characters in the wheel section of LCD. Spin button is given higher priotity interrupt then the bet button. Timer 1 is used to check the activity time out. Activity time out is set to 15 seconds.

Figure 2.2: LCD Display

Timing requirements for the system are

- the response on button pressed should reflect on LCD within 1 sec.
- the wheel spinning should not be so fast that the change of symbols on the screen is not obserable.
- the wheel spinning should not be so slow that player gets enough time to stop by seeing symbol at screen.

Game Logic:

- pressing bet button increases bet
- pressing spin button toggles the spin functionality
- when spin is stopped and the wheels match the reward pattern, the balance is increased with reward
- when spin is stopped and the wheels don't match the reward pattern, the bet value is deducted from balance
- player wins the game, if the balance is reached to max value 10,000
- player loses the game, if the balance becomes zero.

Symbols used for spinning wheels are \$ (dollar), Y (Yen), # (pound), $\sum$ (summation) and π (pi). There are three placeholder in LCD for 3 wheels. Each of these values are initialized with random seed when system is reset. The three wheels spin at differnt rate, 2nd wheel's spin is twice slower than first and 3rd wheel spins trice slower than first. The reward is matched with specific patterns and they are listed below.

Reward Patterns:

- $\pi\ sym\ sym = bet * 5$ [pi and other two same symbol except π]
- \$\$\$ $= bet * 10$
- $YYY = bet * 20$
- $\#\#\# = bet * 30$
- $\Sigma\Sigma\Sigma =$ bet * 50
- $\pi\pi\pi = bet * 100$

The probability of reward pattern can be expressed as $\frac{9}{5!}$.

The main loop intializes the values and runs SM_SpinWheel() function in infinte loop. SM_SpinWheel checks for spin is started or stopped.When started, it updates the spinning wheels with delay of 100 ms. When stopped it updates the reward win and balance. When spin is stoppedactivity timeout timer is started. When spin gets started the timer is stopped. The flow chart of main loop is shown in figure 2.3.

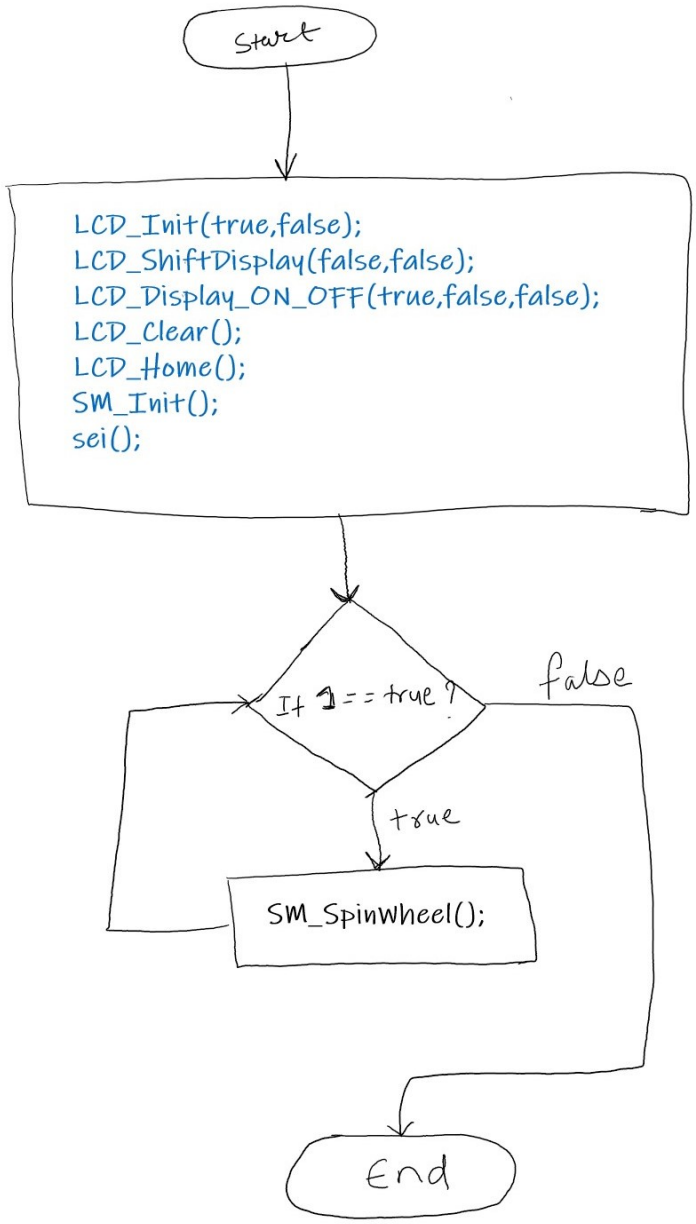

Figure 2.3: Main Loop flow chart

The spin button is mapped to external interrupt 0. The flow chart of ISR0 is shown in figure 2.4.

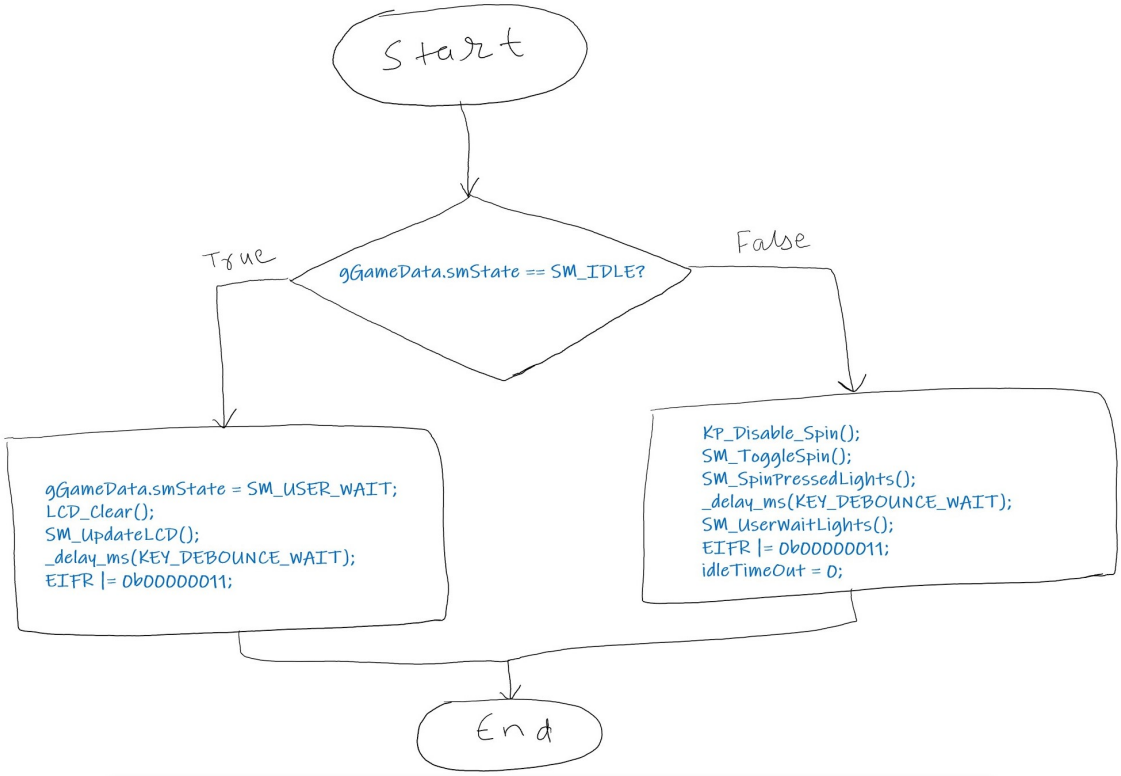

Figure 2.4: ISR0 / spin button flow chart

The bet button is mapped to external interrupt 1. The flow chart of ISR1 iss shown in figure 2.5.

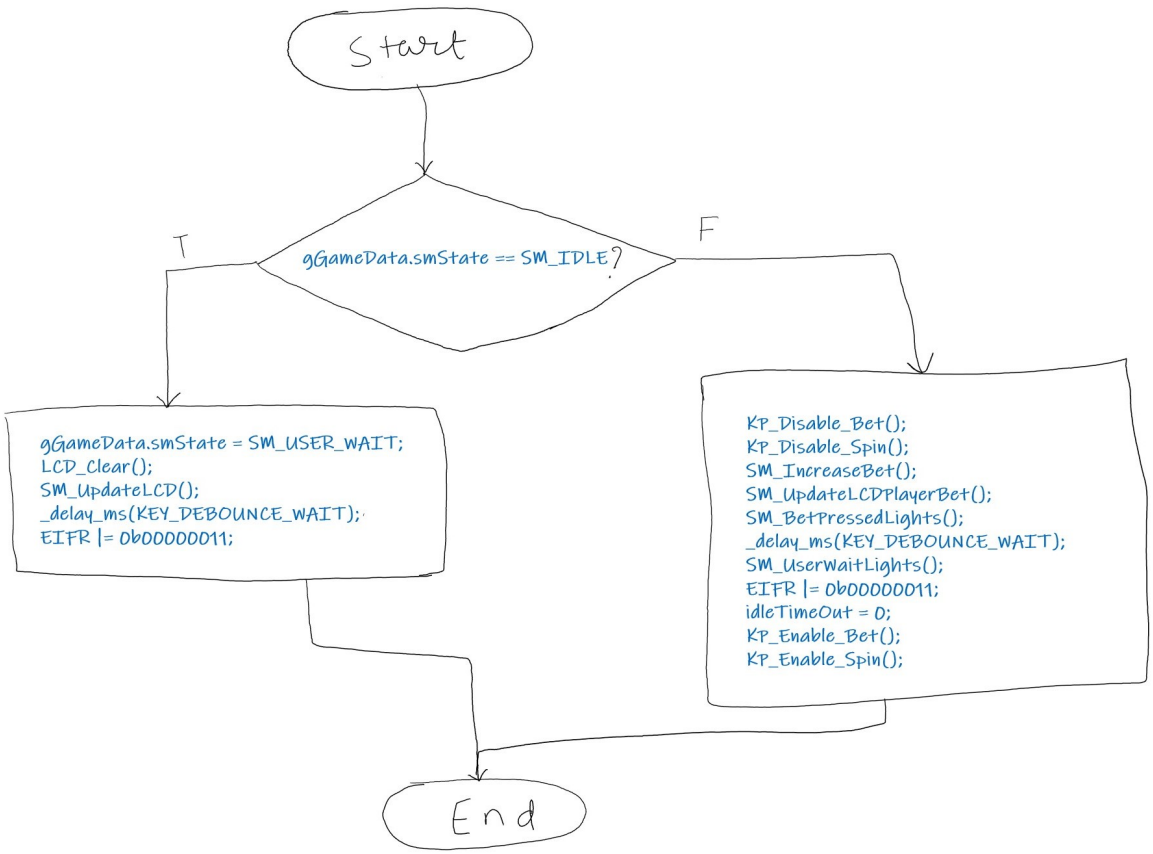

Figure 2.5: ISR1 / bet button flow chart

Timer 1 is used for checking the inactivity of player. If the inactivity is for more than 20 sec. The screen throws "Press to Play" to message. The flow chart for ISR for Timer is shown in figure 2.6.

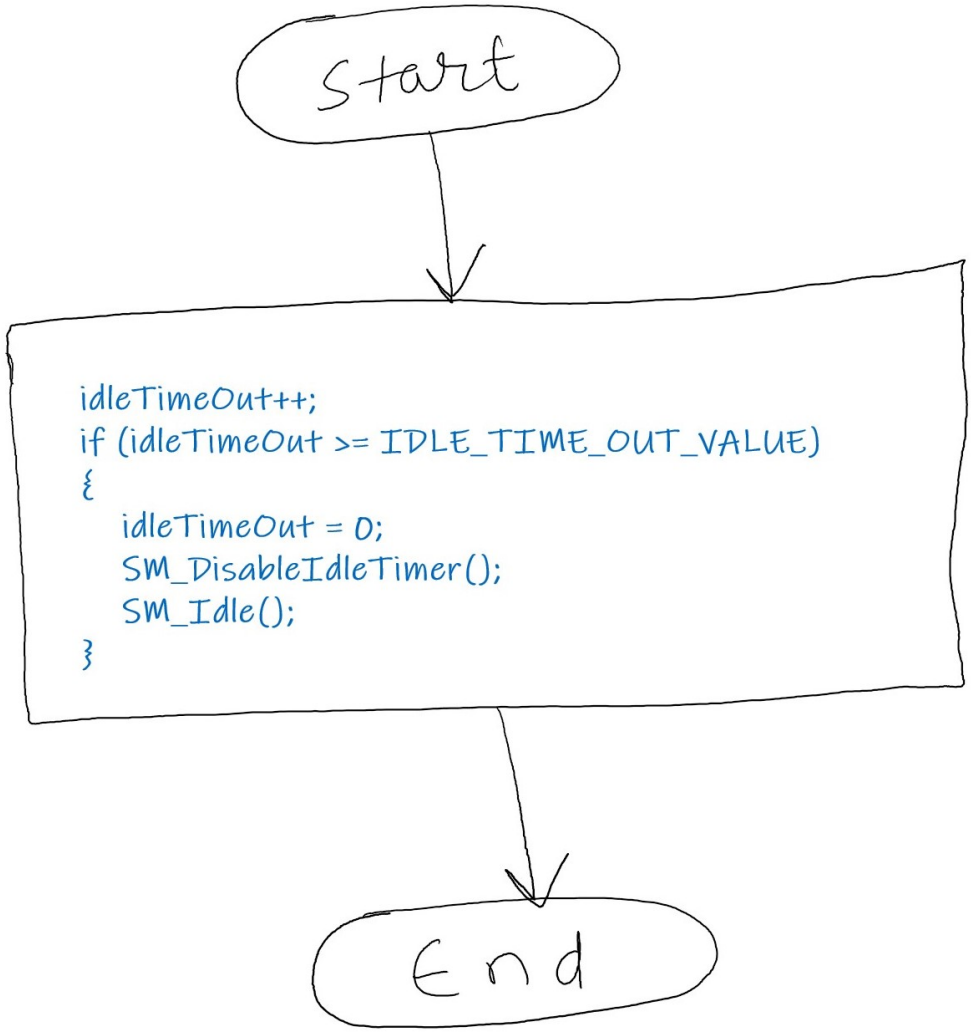

Figure 2.6: ISR Timer0 / Activity timeout flow chart

There are 5 states in this design, and they are SM_INIT, SM_USER_WAIT, SM_IDLE_TIMER_START, SM_SPIN, SM_IDLE. The state transition is shown in figure 2.7.

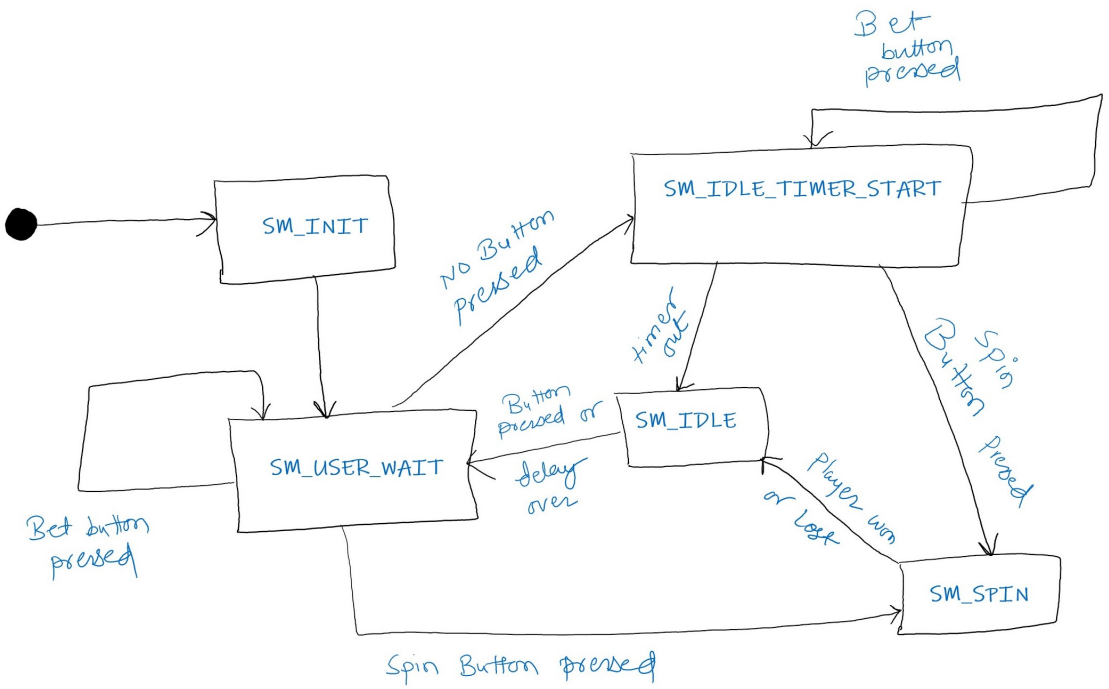

Figure 2.7: ISR Timer0 / Activity timeout flow chart

Chapter 3

Testing

Black box and white box testing is done for the project. Codes were modified to replicate the desired testing scenarios. The list of test cases are listed below in tabular form.

Testing Id	Test Case	Method	Results and Inference
1	Spin Button Pressed Response • Spin Start on pressing • Spin Stop on pressing	Manual black box testing. Checked update of spin section on LCD	Passed
2	Spin button should not work immediately after spin is stopped. Spin button should be activated only after the winning result and balance are updated on screen.	Added delays in the code to verify	Passed
3	Bet button pressing should increase bet value. After reaching maximum value, the value should be the minimum value.	Pressing bet button and checking the updated values on the LCD	Passed
4	Bet button should be inactive when spin is on. The bet value should not change when spinning is on	Pressing bet button while spin is on.	Passed
5	Balance should increase by proper reward value and decrease by bet value.	Modified code with less permutation to check proper mapping of reward amount of the pattern.	Passed
6	The balance should not underrun minimal value of 0 and should not overrun maximum value of 10000	Modified code with large reward values to check ceil overrun. Modified code with large bet and zero reward to check underrun.	Passed
7	Winning value should match specified value matching with the pattern.	Modified code to slow turn the spin, so that it can be stopped at desired pattern.	Passed
8	Timing bench marking between spin stop and update of LCD with wheel position, balance and winning reward.	Adding timers in code to get time difference. Activating timer in ISR of bet button and stopping the timer after update of LCD.	To be determined

The Worst Case Execution Time WCET can be considered for the time of response when the spin is stopped and the values get updated. Consdering 1Mz clock speed, 37 μs write and command time for LCD, WCET can be calculated from code walk through. In function SM_SpinWheel() in file SlotMachine.c, a while loop runs when spin is on, i.e. while(SPIN_ON == spinReels). It is considered the main routine is exactyly at this point when ISR routine for spin button is pressed. The longest code path till the LCD update occurs give the WCET. No reward pattern is considered for the longest code traversal. The calculated WCET rounds off to 104 ms.

43      VERY IMPORTANT
44      To do a 16-bit write, the high byte must be written before the low
            byte.
45      For a 16-bit read, the low byte must be read before the high byte.
```

```
46
47      It is important to notice that accessing 16-bit registers are
            atomic operations.
48      If an interrupt occurs between the two instructions accessing the
            16-bit register,
49      and the interrupt code updates the temporary register by accessing
            the same or any
50      other of the 16-bit Timer Registers, then the result of the access
            outside the
51      interrupt will be corrupted. Therefore, when both the main code and
             the interrupt
52      code update the temporary register, the main code must disable the
            interrupts during
53      the 16-bit access.

Chapter 5

Critical evaluation and Conclusion

All the major aspects and functionalities of the project are developed.The developed project works almost perfectly as intended. The realised system is shown in the figure 5.1. There is one unfinished work of maximum bet. A button which can set the bet value to maximum, instead of hitting bet button multiples times to reach the max value. The c functions for this is in place but are left unimplemented. The unimplemented code doesn't have any observable major impact on any such functionalities. The button bounce could be addressed by adding extra capacitive circuit for the buttons. The bench marking of time between the spin stop and LCD update hasn't been achieved. There is enough room to add further functionalities to it. One good feature would be to provide interface to allow setting of desired symbols and desired patterns for reward.
